Understanding Differential Equations

What Is a Differential Equation?

A differential equation is an equation that involves an unknown function and its derivatives. It expresses the relationship between the function and its rates of change. Differential equations are used extensively to model physical situations such as motion, heat transfer, population growth, and more. Example: $\frac{dy}{dx} = 3x^2$ This simple differential equation relates the derivative of y with respect to x to the variable x .

Types of Differential Equations

Differential equations are classified based on order, linearity, and whether they are homogeneous or nonhomogeneous:

- Order: The highest derivative present in the equation. For example, if the highest derivative is second order, the equation is called a second-order differential equation.
- Linearity: Whether the unknown function and its derivatives appear to the first power and are not multiplied together.
- Homogeneity: Whether the equation equals zero (homogeneous) or a non-zero function (nonhomogeneous).

Common Types:

Type	Description	Example
First-Order Linear	Involves first derivative, linear in y	$\frac{dy}{dx} + y = e^x$
Separable Equations	Variables can be separated	$\frac{dy}{dx} = xy$
Homogeneous Equations	Can be made into a function of y/x	$y' = \frac{y}{x}$
Second-Order Linear	Involves second derivatives	$y'' + 3y' + 2y = 0$

Solving Elementary Differential Equations

Methods for First-Order Differential Equations

Many first-order differential equations can be solved using specific techniques. Below are some common methods:

1. Separable Differential Equations

These equations can be written in the form: $\frac{dy}{dx} = f(x)g(y)$ Solution Steps: 1. Rearrange to

separate variables: $\int \frac{1}{g(y)} dy = \int f(x) dx$ 2. Integrate both sides: $\int \frac{1}{g(y)} dy = \int f(x) dx$ 3. Solve for y . Example: Solve $\frac{dy}{dx} = xy$. Solution: $\frac{dy}{y} = x dx$ $\rightarrow \int \frac{1}{y} dy = \int x dx$ $\rightarrow \ln|y| = \frac{x^2}{2} + C$ $\rightarrow y = \pm e^{\frac{x^2}{2} + C} = Ae^{\frac{x^2}{2}}$

2. Linear Differential Equations

Standard form: $\frac{dy}{dx} + P(x)y = Q(x)$ Solution: 1. Find the integrating factor: $\mu(x) = e^{\int P(x) dx}$ 2. Multiply the entire differential equation by $\mu(x)$. 3. Recognize that the left side becomes the derivative of $\mu(x)y$: $\frac{d}{dx}[\mu(x)y] = \mu(x)Q(x)$ 4. Integrate both sides to find y . Example: Solve $\frac{dy}{dx} + 2y = e^{3x}$. Solution: - Integrating factor: $\mu(x) = e^{\int 2 dx} = e^{2x}$ - Multiply through: $e^{2x} \frac{dy}{dx} + 2e^{2x}y = e^{2x}e^{3x} = e^{5x}$ - Recognize: $\frac{d}{dx}[e^{2x}y] = e^{5x}$ - Integrate: $e^{2x}y = \int e^{5x} dx = \frac{1}{5}e^{5x} + C$ - Solve for y : $y = e^{-2x} \left(\frac{1}{5}e^{5x} + C \right) = \frac{1}{5}e^{3x} + Ce^{-2x}$

Methods for Second-Order Differential Equations

Second-order differential equations are more complex but follow specific solution techniques:

1. Homogeneous Equations with Constant Coefficients

Standard form: $ay'' + by' + cy = 0$ Solution: 1. Write characteristic equation: $ar^2 + br + c = 0$ 2. Find roots r . 3. Write the general solution based on roots: - Real and distinct roots: $y(t) = C_1 e^{r_1 t} + C_2 e^{r_2 t}$ - Repeated roots: $y(t) = (C_1 + C_2 t) e^{r t}$ - Complex roots: $r = \alpha \pm \beta i$ $y(t) = e^{\alpha t} (C_1 \cos \beta t + C_2 \sin \beta t)$

Boundary Value Problems (BVPs)

What Are Boundary Value Problems?

Boundary value problems involve differential equations along with specified conditions at the boundaries (endpoints) of the domain. Unlike initial value problems, which specify the solution at a single point, BVPs set conditions at multiple points. Example: Solve $y'' + y = 0$, with boundary conditions: $y(0) = 0$, $y(\pi) = 0$

Methods to Solve Boundary Value Problems

1. Analytical Methods

- Direct Integration: Applicable for simple linear equations with constant coefficients. - Eigenfunction Expansion: Used when the BVP relates to physical systems like vibrating strings or heat conduction.

2. Shooting Method

- Guess the initial derivative value. - Integrate the differential equation. - Adjust the guess until boundary conditions are satisfied.

3. Finite Difference Method

- Approximate derivatives using difference equations. - Set up a system of algebraic equations. - Solve the system for the approximate solution.

Solving Boundary Value Problems: Examples

Example 1: Simple BVP

Solve: $y'' + y = 0$ with boundary conditions: $y(0) = 0, \quad y(\pi) = 0$ Solution: - General solution: $y(t) = C_1 \cos t + C_2 \sin t$ - Apply boundary conditions: $y(0) = C_1 \cdot 1 + C_2 \cdot 0 = 0 \Rightarrow C_1 = 0$ $y(\pi) = 0 + C_2 \sin \pi = 0 \Rightarrow 0 + C_2 \cdot 0 = 0$ - Since $\sin \pi = 0$, any C_2 satisfies the boundary condition, but to have non-trivial solutions, C_2 can be any value. - Eigenfunctions: $y(t) = C \sin t$ - Eigenvalues: The boundary conditions lead to solutions when $y(t)$ is a sine function, which is typical of vibrating strings fixed at both ends.

Example 2: Heat Equation Boundary Problem

Suppose the temperature $u(x,t)$ along a rod of length L satisfies: $\frac{\partial u}{\partial t} = k \frac{\partial^2 u}{\partial x^2}$ with boundary conditions: $u(0, t) = 0, \quad u(L, t) = 0$ and initial temperature distribution $u(x,$
