Sample Biostatistics Questions with Answers

Basic Knowledge Questions

Q1: What is the difference between descriptive and inferential statistics? Answer: Descriptive statistics summarize and describe the main features of a dataset, such as measures of central tendency (mean, median, mode) and variability (range, variance, standard deviation). Inferential statistics, on the other hand, use sample data to make generalizations or predictions about a larger population, often through hypothesis testing and confidence intervals.

Q2: Define the term 'p-value' in hypothesis testing. Answer: A p-value is the probability of obtaining an observed result, or one more extreme, assuming that the null hypothesis is true. It helps determine the statistical significance of the findings; a smaller p-value indicates stronger evidence against the null hypothesis.

Probability and Distributions

Q3: What is the Central Limit Theorem? Answer: The Central Limit Theorem states that, given a sufficiently large sample size, the sampling distribution of the sample mean will be approximately normally distributed, regardless of the shape of the population distribution. This principle underpins many inferential statistical methods.

Q4: Which distribution is most appropriate for modeling the number of events happening in a fixed interval of time? Answer: The Poisson distribution is most appropriate for modeling the number of events occurring in a fixed interval, especially when events occur independently and at a constant average rate.

Hypothesis Testing and Confidence Intervals

Q5: When is it appropriate to use a paired t-test? Answer: A paired t-test is used when comparing two related samples or measurements taken from the same subjects under different conditions, such as before-and-after studies or matched pairs.

Q6: How is a 95% confidence interval interpreted? Answer: A 95% confidence interval provides a range within which we are 95% confident that the true population parameter (such as the mean) lies, based on the sample data.

Comparative and Correlation Analysis

Q7: What is the main difference between correlation and causation? Answer: Correlation indicates a statistical association between two variables, but it does not imply that one causes the other. Causation implies a cause-and-effect relationship, which requires further evidence beyond correlation.

Q8: Which test would you use to compare proportions between two independent groups? Answer: The Chi-square test of independence or Fisher's exact test (for small sample sizes) is used to compare proportions between two independent groups.

Regression and Advanced Methods

Q9: What does the coefficient of determination (R-squared) indicate in regression analysis? Answer: R-squared indicates the proportion of variability in the dependent variable that can be explained by the independent variable(s) in the regression model. Values range from 0 to 1, with higher values indicating better model fit.

Q10: In logistic regression, what is the primary outcome variable? Answer: The primary outcome variable in logistic regression is binary (dichotomous), such as presence or absence of disease, success or failure.
